## Case Study: Multifamily with Complex Envelope

This case study shows the relative accuracy of the easy Condense energy modeling platform compared to traditional Energy Plus modeling. This particular case study looks at a multifamily apartment complex that includes a clubhouse with light commercial spaces. The apartment buildings have complex exterior walls that jog in and out. The Condense energy results varied from traditional modeling results by only 0.1% to 0.6% (depending on location), yet Condense was much quicker and easier to use, with far less opportunity for human error in entering inputs.

This project was part of a series of similar projects we modeled for HUD MIP reduction documentation. All were approved by the HUD reviewer.

The project was a typical low rise multifamily development near Austin, Texas, with 3-story multi-unit buildings in a variety of orientations and unit combinations, and a central amenity center that includes offices, fitness room, and lounge space.

	Cooling Setpoint Schedule	Standard

HVAC systems were typical air conditioners with electric heat, and energy specs such as insulation and lighting were typical. The original project had some variation in specs between multifamily unit types, but for this case study we normalized them across the project as listed above. The amenity center was similar but with lighting at 0.85 w/sf.

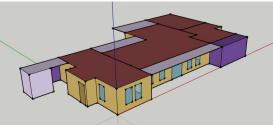

Building Type I

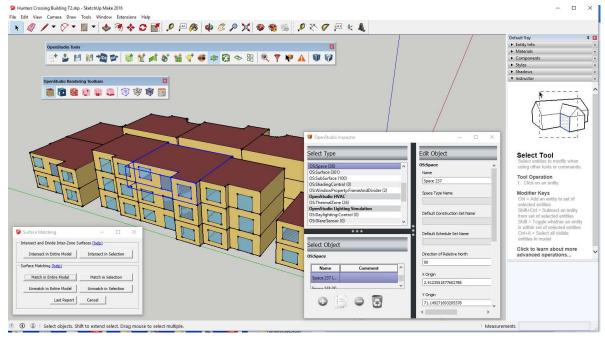

Building Type II

Amenity Center with shading

The traditional models started with full building 3D CAD models, with each zone drawn and placed, including detailed wall layout with jogs and detailed window placement. The clubhouse model includes several shading elements (covered porches).

These models were created in Sketchup 2016, then, using an Open Studio plugin compatible with that Sketchup version, they were translated into Energy Plus Open Studio models with thermal zones and matching of adjacent surfaces to model heat transfer between zones. Many things can go wrong during this step, and must be troubleshooted: a stable version of Sketchup that is compatible with the Open Studio plugin must be maintained, 3d model surfaces must be complete and not overlapping, windows must drawn and placed flat on exterior walls then cut out of the walls, adjacent surfaces must be matched to translate into the idf file, zones must be identified by clicking in the 3d model.

The Open Studio files were then opened in Open Studio, and HVAC systems, lighting, insulation and other Energy Plus components were wired up. These components must all be selected from libraries and applied to each zone. HVAC systems must be designed with proper branching and integration of subcomponents.

Since there were two common multifamily building types with minor variations such as orientation, we exported the common idf files from Open Studio and used the Energy Plus idf editor to make the minor adjustments to each model. Then we ran each building in Energy Plus with its correct weather file.

... or walk through space by space. There is zero drawing required, no jockeying between CAD programs, and just a few critical geometric inputs (square footage, estimated length of exposed walls only (non-exposed walls are ignored), and estimated window area). So, on geometry, Condense is MUCH faster and more foolproof than the traditional approach. When it comes to specifications (lighting, insulation, HVAC systems), Condense translates your project basics (location, year of construction, etc.) to predict what specifications are most likely in your building. So you start with a completely specified predictive model. You can then check the specs, such as your HVAC system type and equipment efficiency rating, but Condense guides you through in a way that is simple and understandable even to non-experts.. Your simple inputs are translated by powerful algorithms into the 3D and expert engineering inputs required by Energy Plus. You will get automatically produced Energy Plus models, with results automatically summarized, long-term financial outlook, and more.

visit us at **Condense.cloud** 

### **Results Comparison: Austin, TX**

- full traditional Energy Plus model from 3d CAD
- Condense

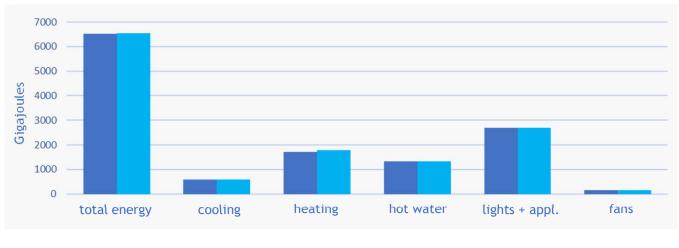

We compiled all results from the traditional vs. Condense run. Above you can see results for the model located in Austin, TX, with appropriate weather files. The total margin of error was only 0.1%, with a margin of 0.5% for heating and 0.5% for cooling. These are negligible margins of error that show that the Condense model is equivalent to a traditional Energy Plus model in its ability to predict both overall building performance, and relative savings from energy efficiency strategies.

### **Results Comparison: Richmond, VA**

- full traditional Energy Plus model from 3d CAD
- Condense

To test a range of climate zones, we also ran the same models in Richmond, VA, with appropriate weather files. The total margin of error was only 0.6%, with a margin of 3% for heating and 0.1% for cooling. The main discrepancy was in the heating, where Condense slightly overestimated heating. However, this is still in a range that allows accurate prediction of savings from energy efficiency strategies.
